RE: Cargill Fertilizer, Inc.
Riverview Plant Expansion PSD Application
PSD-FL-315 0590008-036-AC

Dear Mr. Linero:

On March 15, 2001, Cargill Fertilizer met with you, Syed Arif and Cleve Holladay to discuss the PSD application for the Riverview plant expansion. During the meeting, several potential issues were discussed, and it was agreed to provide additional information to the Department. This additional information is presented in this letter and in the attachments. The information is presented below by subject area.

Sulfuric Acid Plants

The Department indicated that Farmland Industries accepted a SO₂ emission limit for a new H₂SO₄ plant of 3.5 lb/ton as a 3-hour average. Cargill's proposed emission limit is 3.5 lb/ton as a 24-hour average. The Department requested that Cargill further address the ability to accept a 3-hour averaging time limit, and to quantify any economic or other impacts upon the operations.

The proposed 3.5 lb/ton limit for the Nos. 8 and 9 H₂SO₄ Plants is already much more restrictive than the current 4.0 lb/ton limit. Cargill is required to operate the plants with some margin or safety factor to compensate for upsets, in order to ensure the emission limit is not exceeded. With a 24-hour averaging time, upsets that temporarily increase emissions can be balanced by time operating at a lower emissions limit. In order to operate the two plants at 3.5 lb/ton with a 3-hour averaging time, with an acceptable margin of safety, the addition of an increased amount of cesium catalyst beyond what was initially budgeted for this project would be required. This additional catalyst would increase the project costs by approximately \$400,000.

The Department was also interested in the test data from the No. 9 H₂SO₄ Plant, which now has test data after the installation of cesium catalyst. This project was initiated with a goal of achieving an emissions limit of 3.5 lb/ton, 24-hour average, and would not be sufficient to meet a limit based on a 3-hour averaging time. Test data from the No. 9 H₂SO₄ Plant before the installation of cesium catalyst is presented in the PSD application. Test data after installation of the cesium is presented in Attachment A to this letter.

BUREAU OF AIR REGULATION

Summary of Proposed BACT Limits

A summary table of Cargill's proposed BACT limits, as well as the range of emission limits contained in previous BACT determinations, is provided in Attachment B. The previous determinations include the recently issued US Agri-Chemicals and White Springs Agricultural Chemicals PSD permits.

BACT for SO₂ from Fuel Oil Burning

The application did not specifically address BACT for SO₂ emissions due to fuel oil burning in the process dryers. The emissions units for which a BACT analysis is required consist of the EPP Plant, AFI Plant, and No. 5 DAP Plant. Each of the emissions units are currently permitted to burn fuel oil as a backup fuel for only 400 hr/yr. The maximum sulfur content of the fuel oil is 0.5%. As such, the potential SO₂ emissions from each emissions unit is less than 10 TPY.

The only feasible alternative BACT is the use of lower sulfur fuel oil, i.e., fuel oil with a maximum sulfur content of 0.05%. However, this would reduce potential SO₂ emissions by only about 15 TPY. In addition, more fuel usage would result due to the lower heating value of 0.05% sulfur fuel oil (about 136,000 Btu/gal vs. about 140,000 Btu/gal for 0.5% sulfur oil). Additional fuel oil usage is not desirable in the current national situation of reduced fuel oil and natural gas availability. Considering that fuel oil is used only as a backup, when natural gas is not available, and fuel oil burning is limited to 400 hr/yr from each emissions unit, the current fuel oil with a maximum sulfur content of 0.5% is considered as BACT for these sources.

Revisions to SO₂ Class II and Class I Modeling Analysis

Revisions to the SO₂ PSD Class II and Class I emission inventories for several other sources have been made, and the dispersion models have been re-executed with the revised inventories. This resulted in slightly revised impacts from those presented in the PSD application. The revised tables in Section 6.0 and Appendix F with the revised inventories and impacts are provided in Attachment C.

AQRV Analysis for Sulfuric Acid Mist

The Department requested that Cargill review the PSD application and ensure that the effects of sulfuric acid mist (SAM) emissions are addressed in the air quality related values (AQRV) analysis. The AQRV analysis was presented in Section 7.0 of the PSD report. Review of this section indicates that the impact of SAM emissions in the vicinity of the Cargill facility was addressed in regards to soils, but not addressed for vegetation. The PSD Class I analysis does address SAM impacts on soils and vegetation, but not wildlife. These impacts are addressed below.

SAM EMISSIONS

SAM emissions for the proposed Cargill project are presented in Attachment D (see Table 6-7b). The derivation of SAM emissions from the affected fuel burning sources at Cargill is also presented in Attachment D.

IMPACTS OF SAM EMISSIONS ON VEGETATION IN THE VICINITY OF CARGILL

The predicted maximum increase in the 1-hour, 3-hour, 8-hour, 24-hour, and annual SAM concentrations in the vicinity of the Cargill plant due to the proposed plant expansion are 13.1, 9.0, 6.1, 2.9 and 0.25 µg/m³, respectively (see Table 6-22 in the attached Appendix C).

SAM can be emitted directly from sulfuric acid plants and fossil fuel combustion sources, or can be formed as acidic precipitation or acid rain due to SO₂ emissions from these sources. SO₂ is oxidized in the atmosphere and dissolves in rain forming sulfuric acid mist which falls as acidic precipitation (Ravera, 1989). During the last decade, much attention has been focused on acid rain. Acidic deposition is an

ecosystem-level problem that affects vegetation because of some alterations of soil conditions such as increased leaching of essential base cations or elevated concentrations of aluminum in the soil water (Goldstein *et al.*, 1985). Although effects of acid rain in eastern North America have been well published and publicized, detrimental effects of acid rain on Florida vegetation are lacking documentation.

Although concentration data are not available, sulfuric acid mist has been reported to yield necrotic spotting on the upper surfaces of leaves (Middleton *et al.*, 1950). Because the project's SO₂ and SAM impacts on the local air quality are predicted to be low, the project's impacts on vegetation in the Cargill vicinity are not expected to be significant. It is important to realize that the modeled SAM concentrations represent a worst-case scenario, which, in reality, are not likely to occur. As described in the PSD application for SO₂ impacts, actual measured ambient concentrations in the area are much lower than maximum modeled concentrations. Moreover, Cargill's SO₂ emissions represent only a small fraction of the total SO₂ emissions emitted in the area.

IMPACTS OF SAM EMISSIONS ON WILDLIFE IN THE CHASSAHOWITZKA CLASS I AREA

The maximum SAM concentrations due to the Cargill expansion project's emissions predicted at the PSD Class I area of the Chassahowitzka National Wilderness Area (CNWA) are presented in the revised Table 7-1 attached (see Attachment D). These results are based on using the CALPUFF model.

A wide range of physiological and ecological effects to fauna has been reported for gaseous and particulate pollutants (Newman, 1981; Newman and Schreiber, 1988). The most severe of these effects have been observed at concentrations above the secondary ambient air quality standards. Physiological and behavioral effects have been observed in experimental animals at or below these standards. For impacts on wildlife, the lowest threshold values of SO₂, NO₂, and particulates which are reported to cause physiological changes are shown in Table 7-4 of the PSD application. These values are up to orders of magnitude larger than maximum concentrations predicted for the Cargill expansion for the Class I area. No effects on wildlife AQVs from SO₂, NO₂, and particulates are expected. The proposed project's contribution to cumulative impacts is negligible.

Truck Traffic Emissions and Impacts

Truck traffic emissions were not explicitly modeled in the air quality impact analyses. Rather the air quality impacts for PM10 for these sources were assumed to be included in the background concentrations developed for the Project. As discussed in Section 4.2 of the PSD application, the PM10 background concentrations were based on monitoring data collected by the Department at Gardiner Park, Riverview, which is located immediately adjacent to Cargill's Riverview facility. The highest annual and sixth-highest 24-hour average concentrations occurring over a three-year period from 1998 through 2000 were used to represent background concentrations from sources not explicitly modeled. However, it should be noted that this PM10 monitor is not a true background monitor and the selected background values are not considered true background concentrations because this monitor is impacted by existing sources, such as those at the Cargill facility, that are included explicitly in the model. In addition, because this monitor is located adjacent to the Cargill facility, this monitor measures PM10 concentrations from those sources not explicitly modeled, such as truck traffic emissions. As a result, when added to the modeled sources' impacts, the selected background concentrations provide reasonable and still conservative estimates for assessing compliance with ambient air quality standards.

All dispersion modeling electronic files were posted Friday, March 23 on the Golder FTP site:
<ftp://external.golder.com/Gainesville/CargillRiverview/>

Thank you for considering this information. If you require anything further, please do not hesitate to call me at (352) 336-5600 x545.

Sincerely,

	13.1	210.6	294	95111924

^a Based on 5-year meteorological record, Tampa (surface)/ Ruskin (upper air), 1991 to 1995

^b Relative to No. 9 Sulfuric Acid Plant stack.

^c Maximum concentrations were predicted to be less than zero at all receptors.

Note: YYMMDDHH = Year, Month, Day, Hour Ending

HSH = Highest, Second-Highest

**Table 6-18. Maximum Predicted Concentrations for All Sources Compared to the PSD Class II Increment
- Refined Analysis**

Pollutant/ Averaging Time	Concentration ^a (ug/m ³)	Receptor Location ^b		Time Period (YYMMDDHH)	PSD Increment (ug/m ³)

Fuel oil	0.2 lb/10 ³ gal	0.11	0.023	--	--	--	--
Natural gas	5.5 lb/10 ⁶ ft ³ e	--	--	0.440	1.927	--	--
Worse-Case Combination of Fuels		--	--	--	--	0.44	1.93

Footnotes:

Particulate matter emissions through the common plant stack are included in Table 2.5

^a Based on the heat content of fuel oil of 140,000 Btu/gallon.

^b Based on the heat content of natural gas of 1,000 Btu/scf.

^c Emission factors for fuel oil are based on AP-42, Section 1.3, September 1998. Emission factors for natural gas are based on AP-42, Section 1.4, July 1998.

^d S denotes the weight-percent of Sulfur in fuel oil; Maximum sulfur content = 0.5%.

^e Based on methane comprised of 52% total VOC.

Table 2-8. Maximum Emission Rates Due to Fuel Combustion for the Dryer at the AFI Plant
